

SIMATS ENGINEERING

ASSESSMENT TOOL 2

COURSE NAME: Database Management Systems

COURSE CODE: CSA0504

COURSE OUTCOME COVERED

CO1: Analyse DBMS architecture, different data models, schema types, and design ER/EER diagrams, relational schemas for case-based scenarios by identifying entities and relationships. (BL1, BL2)

Activity Tool : Concept Mapping (Medium)

Assessment Tool Weightage: 20%

QUESTIONS		
Q.N o	Question	Bloom's Level
1	Construct a concept map linking the following terms: DBMS, Schema, Instance, Data Model, ER Diagram, Entity, Attribute, Relationship.	BL2 – Understand
2	Create a concept map for the three-level ANSI/SPARC architecture showing data independence at each level.	BL2 – Understand
3	Map the relationship between file-based systems and database systems, highlighting the problems solved by DBMS.	BL2 – Understand
4	Design a concept map for ER diagram components: entity, weak entity, attribute types, relationship types, and participation constraints.	BL2 – Understand
5	Construct a concept map comparing Hierarchical, Network, and Relational data models with their key properties.	BL2 – Understand
6	Develop a concept map for the EER model showing how it extends the basic ER model with generalization, specialization, and aggregation.	BL2 – Understand

7	Create a visual concept map for the DBMS software architecture, illustrating the flow from user request to data retrieval.	BL2 – Understand
8	Map the data models discussed in CO1 to real-world applications and explain the suitability of each model.	BL2 – Understand
9	Construct a concept map for schemas and instances, showing how they relate to physical and logical data independence.	BL2 – Understand
10	Design a concept map for the roles and responsibilities in a DBMS environment: DBA, End User, Application Developer.	BL1 – Remember

Code of Conduct:

Criteria	Weightage	Level 4 (Exemplary)	Level 3 (Proficient)	Level 2 (Developing)	Level 1 (Beginning)
Concept Identification	25%	Identifies all key concepts from literature accurately and comprehensively	Identifies most key concepts with minor omissions	Identifies limited concepts; some are irrelevant or missing	Fails to identify essential concepts
Linkages	25%	Establishes clear, meaningful, and accurate relationships between concepts	Shows correct relationships with minor gaps	Relationships are weak, unclear, or partially incorrect	No meaningful relationships established

Organization	20%	Concepts are well-structured hierarchically with logical flow and grouping	Mostly organized with minor structural issues	Some organization but lacks clear hierarchy	No logical organization or structure
--------------	-----	--	---	---	--------------------------------------

I **R.Pranathi(192525076)** certify that this submission is my original work and that I have adhered to the guidelines specified for this assessment. I understand that any violation of academic integrity rules will result in disciplinary action.

Signature of the student: Pranathi

RUBRICS FOR CALCULATION:

Integration of Literature	20%	Integrates multiple studies effectively to show connections and comparisons	Shows some integration of literature	Limited integration; mostly isolated concepts	No integration of literature evidence
Clarity	10%	Concept map is clear, neat, visually structured, and easy to interpret	Generally clear with minor readability issues	Clarity is reduced; difficult to interpret in parts	Poorly presented and hard to understand

1. Construct a concept map linking the following terms: DBMS, Schema, Instance, Data Model, ER Diagram, Entity, Attribute, Relationship.

DBMS (Database Management System)

- Software used to create, store, retrieve, and manage databases.
- Ensures data security, consistency, and integrity.

Schema

- The logical structure or blueprint of a database.
- Defines tables, columns, constraints, and relationships.
- Changes rarely.

Instance

- The actual data stored in the database at a particular time.
- Changes whenever data is inserted, updated, or deleted.

Data Model

- A set of concepts used to organize and describe data.
- Defines how data is stored and related.
- Examples: Relational Model, Hierarchical Model.

ER Diagram (Entity-Relationship Diagram)

- A graphical representation of a database.
- Shows entities, attributes, and relationships.
- Used during database design.

Entity

- A real-world object or thing.
- Examples: Student, Employee, Customer.

Attribute

- A property or characteristic of an entity.
- Examples: Student_ID, Name, Age.

Relationship

- Represents the association between two or more entities.
- Example: **Student** enrolls in **Course**.

2. Create a concept map for the three-level ANSI/SPARC architecture showing data independence at each level.

External Level (User View)

- Represents different views for different users.
- Shows only the data required by each user.
- Provides security by hiding unnecessary information.

Conceptual Level (Logical View)

- Describes the complete logical structure of the database.
- Defines entities, relationships, attributes, and constraints.
- Independent of physical storage details.

Internal Level (Physical View)

- Describes how data is physically stored.
- Includes file organization, indexes, and storage methods.
- Focuses on database performance and storage efficiency.

Data Independence

- **Logical Data Independence:** Changes in the conceptual schema do not affect external user views.
- **Physical Data Independence:** Changes in the internal schema do not affect the conceptual schema.

3. Map the relationship between file-based systems and database systems, highlighting the problems solved by DBMS

File-Based Systems

- Stores data in separate files.
- Leads to data redundancy and inconsistency.
- Difficult to access, update, and share data.
- Limited security and backup facilities.
- No data independence.

Database Systems (DBMS)

- Stores data in a centralized database.
- Reduces data redundancy and improves consistency.
- Provides easy data access using SQL.
- Supports security, backup, and recovery.
- Offers logical and physical data independence.

Problems Solved by DBMS

- Eliminates data redundancy and inconsistency.
- Integrates data into a single database.
- Provides efficient data retrieval.
- Controls concurrent access by multiple users.
- Enhances data security.
- Supports backup and recovery.
- Provides data independence.

4. Design a concept map for ER diagram components: entity, weak entity, attribute types, relationship types, and participation constraints.

Entity

- A real-world object or thing that can be identified.
- Represented by a Rectangle.
- Examples: Student, Employee, Department.

Weak Entity

- An entity that cannot be uniquely identified by its own attributes.
- Depends on a strong (owner) entity.
- Represented by a Double Rectangle.
- Example: Dependent (depends on Employee).

Attribute Types

- Simple Attribute: Cannot be divided (e.g., Age).
- Composite Attribute: Can be divided into sub-parts (e.g., Address → Street, City, PIN).
- Single-Valued Attribute: Has only one value (e.g., Roll Number).
- Multi-Valued Attribute: Has multiple values (e.g., Phone Number).
- Derived Attribute: Obtained from another attribute (e.g., Age from Date of Birth).
- Key Attribute: Uniquely identifies an entity (e.g., Student_ID).

Relationship Types

- Shows the association between two or more entities.
- Represented by a Diamond.
- Types:
 - One-to-One (1:1)
 - One-to-Many (1:N)
 - Many-to-Many (M:N)

Participation Constraints

- Specify whether an entity must participate in a relationship.
- Total Participation: Every entity must participate (Mandatory).
- Partial Participation: Participation is optional.

5. Construct a concept map comparing Hierarchical, Network, and Relational data models with their key properties.

Hierarchical Data Model

- Organizes data in a **tree structure**.
- Each child has only one parent.
- Supports **one-to-many (1:M)** relationships.
- Simple but less flexible.

Network Data Model

- Organizes data in a **graph structure**.
- A child can have multiple parents.
- Supports **many-to-many (M:N)** relationships.
- More flexible than the hierarchical model.

Relational Data Model

- Organizes data in **tables (rows and columns)**.
- Tables are connected using **primary and foreign keys**.
- Supports SQL for easy data access.
- Most widely used data model in modern DBMS.

6. Develop a concept map for the EER model showing how it extends the basic ER model with generalization, specialization, and aggregation.

Basic ER Model

- Represents data using **entities, attributes, and relationships**.
- Suitable for simple database design.
- Limited in representing complex real-world scenarios.

Enhanced ER (EER) Model

- Extends the basic ER model by adding advanced concepts.
- Provides better modeling of real-world applications.
- Supports inheritance and abstraction.

Generalization

- A **bottom-up** approach.
- Combines similar lower-level entities into a higher-level entity (superclass).
- Example: Student and Employee → Person.

Specialization

- A **top-down** approach.
- Divides a higher-level entity into specialized sub-entities.
- Example: Person → Student, Employee.

Aggregation

- Treats a relationship as a higher-level entity.
- Used when a relationship participates in another relationship.

Advantages of the EER Model

- Represents complex real-world data more accurately.
- Supports inheritance through generalization and specialization.
- Reduces redundancy and improves database design.
- Makes database models easier to understand and maintain.

7. Create a visual concept map for the DBMS software architecture, illustrating the flow from user request to data retrieval.

User Request

- The user submits a request (SQL query) through an application or interface.
- The DBMS receives the query for processing.

Query Processor

- Checks the syntax and validity of the SQL query.
- Converts the query into an internal format.

Query Optimizer

- Finds the most efficient execution plan.
- Reduces execution time and improves performance.

Execution Engine

- Executes the optimized query.
- Coordinates with storage components to retrieve data.

Storage Manager

- Manages files, indexes, and physical storage.
- Reads the required data from the database.

Data Retrieval

- Retrieves the requested data.
- Returns the result to the user in the required format.

8. Map the data models discussed in CO1 to real-world applications and explain the suitability of each model.

Hierarchical Data Model

- Organizes data in a **tree structure**.
- Best for **one-to-many relationships**.
- **Applications:** File systems, organization charts, XML documents.
- **Suitable because:** Simple hierarchy with one parent for each child.

Network Data Model

- Organizes data in a **graph structure**.
- Supports **many-to-many relationships**.
- **Applications:** Banking systems, airline reservation systems, telecommunication networks.
- **Suitable because:** Handles complex relationships efficiently.

Relational Data Model

- Organizes data in **tables (rows and columns)**.
- Uses **primary and foreign keys** to relate tables.
- **Applications:** Banking, hospital, library, e-commerce, and student management systems.
- **Suitable because:** Easy to manage, secure, and supports SQL queries.

Enhanced ER (EER) Model

- Extends the ER model with **generalization, specialization, and aggregation**.
- **Applications:** University management, HR systems, healthcare systems.
- **Suitable because:** Represents complex real-world scenarios accurately.

9. Construct a concept map for schemas and instances, showing how they relate to physical and logical data independence.

Schema

- A schema is the **blueprint or structure** of a database.
- Defines tables, attributes, relationships, and constraints.
- Changes rarely.

Instance

- An instance is the **actual data** stored in the database at a specific time.
- Changes frequently as data is added, updated, or deleted.

Types of Schemas

- **External Schema:** User-specific view of the database.
- **Conceptual Schema:** Logical structure of the entire database.
- **Internal Schema:** Physical storage structure of the database.

Data Independence

- **Logical Data Independence:** Changes in the conceptual schema do not affect external user views.
- **Physical Data Independence:** Changes in the internal schema do not affect the conceptual schema.

10. Design a concept map for the roles and responsibilities in a DBMS environment: DBA, End User, Application Developer.

Database Administrator (DBA)

- Manages and controls the database system.
- Creates and maintains the database.
- Ensures security, backup, recovery, and performance.
- Controls user access and data integrity.

End User

- Uses the database to retrieve, insert, update, or delete data.
- Generates reports and performs daily operations.
- Interacts with the database through applications.

Application Developer

- Designs and develops database applications.
- Writes and tests SQL queries and programs.
- Creates user-friendly interfaces.
- Maintains and updates applications.

Relationship Between Roles

- DBA → Manages and secures the database.
- Application Developer → Builds applications that access the database.
- End User → Uses the applications to work with the database.
